Measuring Performance in Classification Models

(Birary classification)

Y is either oak 1 reg pos

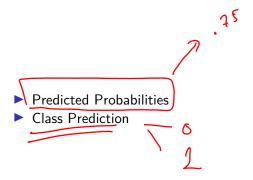

Reading Materials

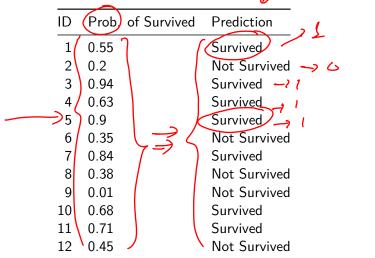

► Max Kuhn. Chapter 11.

Two outcomes of classification models

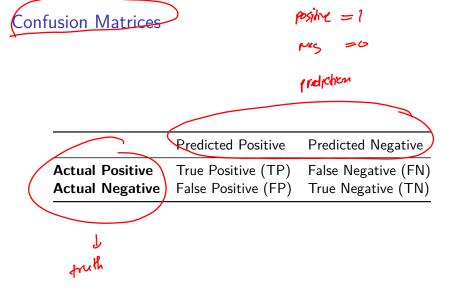

Examples

- Predicting if a passenger in the <u>fitanic is survived</u> or not survived class prediction
- The outcome could look like this.

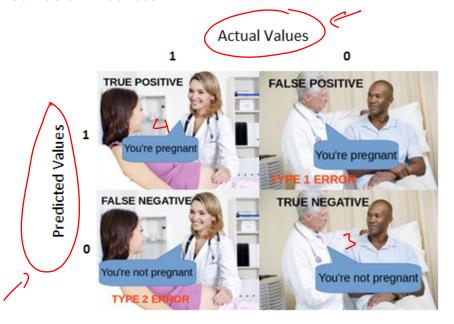

Examples

- Notice that this model predicts "Survived" for passengers with the probabilities of being greater than 0.5
- ▶ 0.5 is called **cut-off value**.
- ► The cuff-off value is set by 0.5 by default.
- ► The cut-off value can be changed by the modeler.

Confusion Matrices

Confusion Matrices - Example

- "Survived" = "Positive"
- "Not Survived" = "Negative"

alwass availso	
I for from Jalidak	
الم الم	

ID	Prob.	of Survived	Prediction	Truth	Evaluation
1	0.55		Survived	Survived	TP ·
2	0.2		Not Survived	Survived	FN
3	0.94		Survived	Survived	P
4	0.63		Survived	Not Survived	FP
5	0.9	·	Survived	Survived	(TP) ·
6	0.35		Not Survived	Not Survived	$TN \leftarrow$
7	0.84		Survived	Not Survived	FP
8	0.38	•	Not Survived	Not Survived	ŢN 🗲
9	0.01		Not Survived	Not Survived	IN C
10	0.68		Survived	Survived	(T) ;
11	0.71		Survived	Survived	(LD)
12	0.45		Not Survived	Survived	FN

Confusion Matrices

	Predicted Positive	Predicted Negative
Actual Positive	5	2
Actual Negative	2	3

Model evaluation from Confusion Matrices

	Predicted Positive	Predicted Negative
Actual Positive Actual Negative	True Positive (TP) False Positive (FP)	False Negative (FN) True Negative (TN)

Misclassification Rate
$$\frac{FN + FP}{Total} = \frac{FN + FP}{TN + TP + FN + FP}$$

$$\frac{Accuracy}{TN + TP + FN + FP}$$

$$\frac{TP}{Actual Positive} = \frac{TP}{TP + FN}$$

$$Specificity = \frac{TN}{Actual Negative} = \frac{TN}{TN + FP}$$

Model evaluation from Confusion Matrices

	Predicted Positive	Predicted Negative
Actual Positive Actual Negative	True Positive (TP) False Positive (FP)	False Negative (FN) True Negative (TN)

Confusion Matrices

	Predicted Positive	Predicted Negative	- e
Actual Positive	TP = 5	FN = 2	
Actual Negative	FP = 2	TN = 3	(5)

Misclassification Rate = 4/12

Accuracy
$$\neq 8/12$$
 ($\frac{543}{12}$)

Sensitivity $\Rightarrow 5/7 = \frac{5}{7}$

Specificity = $3/5$

Precision = $5/7$, F1-Score = $5/7$

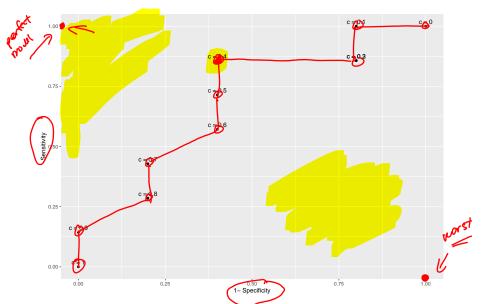

- ► Notice that all of the measures calculated in the last slide are based on the cut-off 0.5
- ▶ What if we change the cut-off value, **c**?

▶ What is the best cut-off value?

Cut-off Values	Sensitivity	Specificity	Balany Accura
c=0	1.0000000	0.0	.5
c = 0.1	1.0000000	0.2	. L best
c = 0.2	0.8571429	0.2	.52
c = 0.3	0.8571429	0.2	-52
c = 0.4	0.8571429	0.6	7285
c = 0.5	0.7142857	0.6	, 653
c = 0.6	0.5714286	0.6	. 585
c = 0.7	0.4285714	0.8	. 614
c = 0.8	0.2857143	0.8	•
c = 0.9	0.1428571	1.0	•
<u>(C=1)</u>	0.0000000	1.0	.5

ROC

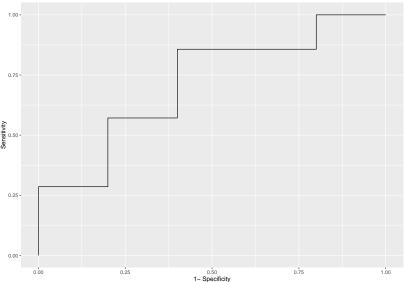

▶ Question: What is the best cut-off value?

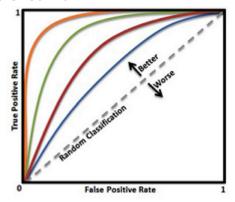

- ▶ **Question**: What is the best cut-off value?
- **Answer**: c = 0.4 is the best cut-off value

- ► Each cut-off value **c** results a pair of (1-Specificity, Sensitivity) or (TP Rate, FP Rate)
- The collections of all these pairs/points for all the cut-off values is the Receiver operating characteristic Curve (ROC Curve)

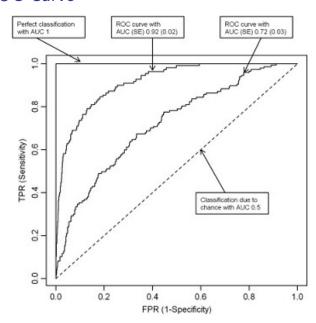

ROC Curve of the example model

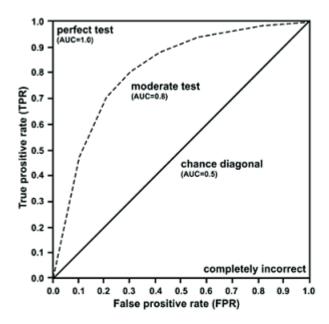

- ▶ The curve is not very smooth because the data is very small
- ► With bigger data, the ROC curve will be very "smooth"

- ▶ The closer the curve to the point (0,1) the better the model
- ightharpoonup The best cut-off value is at the point closest to (0,1)
- ▶ (0,1) is the **perfect point**, resulting 0 misclassification model.
- ► At (0,0) the model predicts everything positive
- ▶ At (1,1) the model predicts everything negative
- ▶ The ROC of the random guess model is the diagonal

ROC Index

▶ ROC Index is the area under the ROC Curve

ROC Index - Area Under the Curve (AUC)

- ▶ The closer the AUC to 1 the better the model
- ▶ The closer the AUC to 1/2 the worse the model
- ▶ Model with AUC = 1/2 is as good as a random guess or guessing by tossing a coin
- ▶ **Question**: What if the AUC less than 1/2? Are models with AUC less than 1/2 **useless**?

Another Question

▶ **Question**: Is the model with the misclassification rate of 100% the most **useless** model?

Answer

- ▶ Question: Is the model with the misclassification rate of 100% an useless model?
- ► Answer: No, by flipping the predictions of the models, one gets the **perfect model** with 0 misclassification rate.

Back to the Question

- ▶ **Question**: What if the AUC less than 1/2? Are models with AUC less than 1/2 **useless**?
- ▶ **Answer**: Model with AUC less than 1/2 could be made to be better by flipping the predictions (if the model predicts positve, flip it to predict negative)

- ▶ In the dataset, the ratio of "Survived" is 7/12 = 58.33%
- ► This mean that if we pick **randomly** a passenger in the this group, the chance of picking a "Survived" passenger is 58.33%
- ▶ **Question**: If we want to pick a "Survived" passenger, is there a better way than pick randomly?

- ▶ Question: If we want to pick a "Survived" passenger, is there a better way than pick randomly?
- ► **Answer**: Yes, we should pick the one with the highest predictied probability.

Order	Predicted Probabilities	True Values
1	0.94	1
2	0.90	1
